

IMMEDIATE RELEASE

Human and Environmental Dangers Posed by Ongoing Weather Modification

SAN DIEGO, July 14, 2016 – Across the US, Canada, and other Western countries, clear azure blue skies are a thing of the past. Our skies are now often tainted with a white haze from jet-laid particle trails. These soon morph into artificial clouds, spread into a haze, sometimes thick enough to make a cloudless sky overcast.

What is being sprayed? What might be the consequences of such spraying on human and environmental health? The authorities are silent.

In a scientific article in *Frontiers in Public Health*, San Diego geoscientist J. Marvin Herndon presents three independent lines of evidence that show the principal substance being sprayed into the air we breathe is coal fly ash. Coal fly ash is a substance too toxic to be allowed to spew from the smokestacks of coal-burning utilities. The ultra-fine particles — less than 2.5 microns across — mix with the air we breathe. Inhaled they become trapped deep in our lungs.

Herndon writes, “The documented public health associations for PM_{2.5} particulate pollution are also applicable to aerosolized coal fly ash which is similar in grain size. These associations include increased hospital admissions, morbidity and premature mortality, low birth weight, lung inflammation and diabetes, risk for cardiovascular disease, lung cancer, lung inflammation and diabetes, risk for stroke, Alzheimer’s disease, onset of asthma, renal functions in older men, and reduced male fertility.”

“The ability of coal fly ash to release aluminum in a chemically mobile form upon exposure to water or body moisture has potentially grave human and environmental consequences over a broad spectrum, including implications for neurological diseases, reduced male fertility, neurological disorders of bees and other creatures, and biota debilitation.”

“The ability of coal fly ash to release heavy metals and radioactive elements upon exposure to body moisture has potentially grave human health implications over a broad spectrum, including, but not limited to, cancer, cardiovascular disease, diabetes, respiratory diseases, and stroke.”

In addition, the author notes that “Toxic methylmercury and ozone-damaging chlorinated-fluorinated hydrocarbons...may be produced from certain types of tropospheric spraying that places coal fly ash in the jet-fuel combustion environment. Experimental verification is warranted.”

The author concludes that from a geophysical perspective, “coal fly ash sprayed in the troposphere warms the atmosphere, blocks heat from Earth radiating back into space, and retards rainfall, which can artificially elevate atmospheric pressures that can block incoming weather fronts, further leading to drought conditions....this activity contributes to global warming.”

“The purpose of this covert activity is unknown to the scientific community and to the public. The time has come for the scientific community and especially the environmental science and

public health communities to understand that a multiplicity of toxic substances is being sprayed into the air breathed by people in many parts of the world and that it will adversely affect virtually all life on Earth.”

Toxic coal fly ash jet-sprayed trails in the air above unaware citizens. The ultra-fine coal fly ash particles do not remain suspended, but mix with the air people breathe. When inhaled the particles with their toxic and radioactive elements become trapped deep in the lungs. The arsenic of coal fly ash can cross the placenta to the fetus.

Jet-sprayed coal fly ash is taking place throughout much of the Western world without health warnings, without informed consent, and without identification of the material being sprayed into the air we all breathe. What are officials being told? That this will stop global warming? No. The spraying causes global warming and its toxins may be causing a slow pandemic, harming virtually all life on Earth.
